**Harvard University**

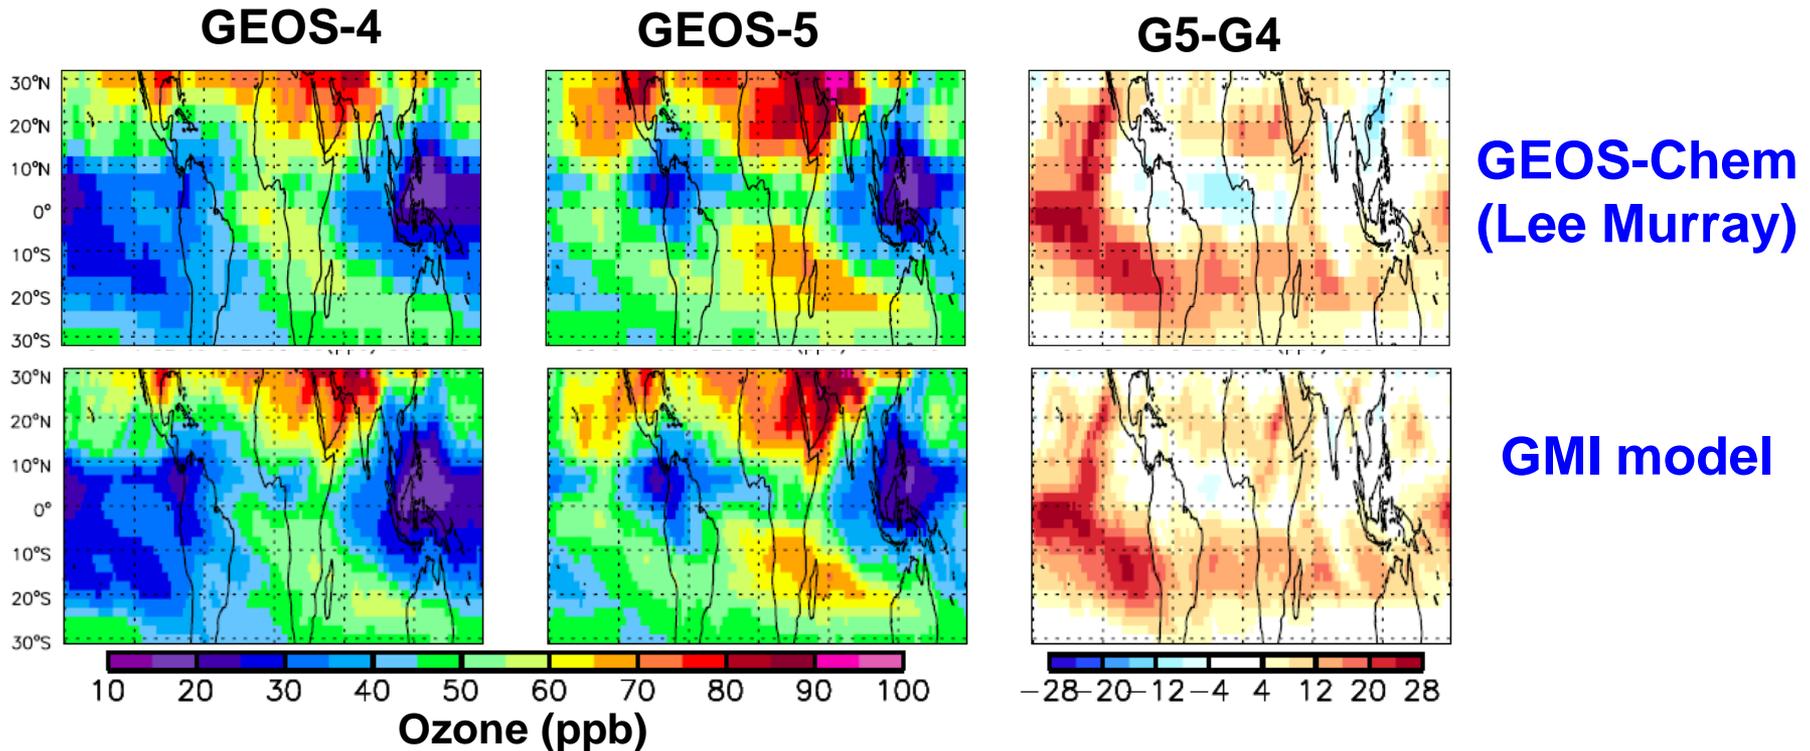

**GEOS-Chem meeting, May 4, 2011.**

**Work funded by NASA MAP and ACMAP programs**

Vertical transport is different in GEOS-5 and GEOS-4 because the convection schemes are different:

- GEOS-4 – Zhang and McFarland (1995) (deep) and Hack et al. (1994) (shallow)
- GEOS-5 – a version of the Relaxed Arakawa Schubert scheme (Moorthi and Suarez, 1992)

Ozone in the tropics at 500 hPa in June, 2005

# MLS, TES, and sondes show that tropical ozone in GEOS-4 is more realistic than in GEOS-5 (example for July 2006)

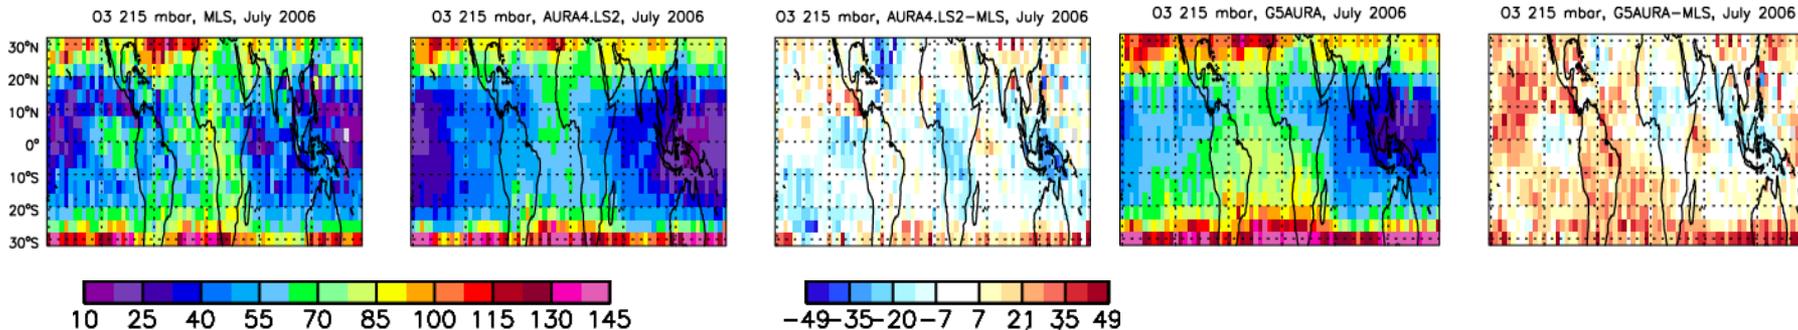

## 215 hPa **MLS**

## GEOS-4

## G4-MLS

## GEOS-5

## G5-MLS

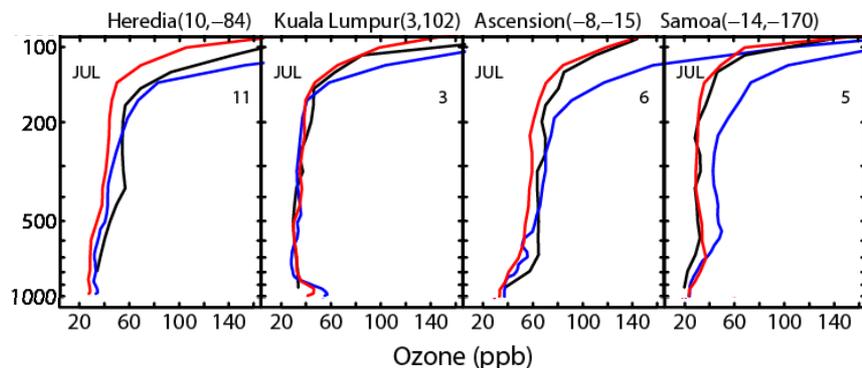

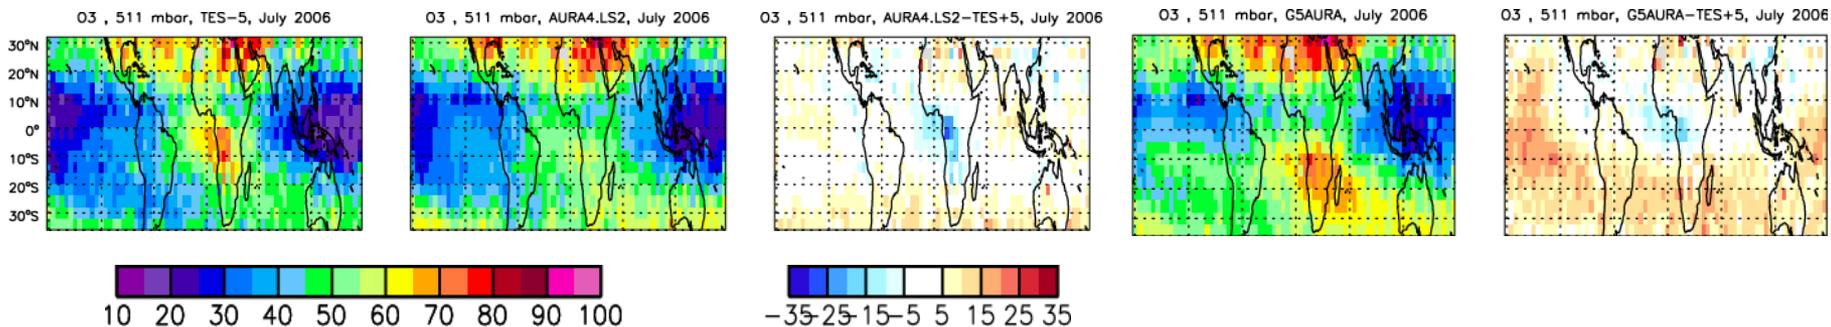

## 500 hPa **TES**

## GEOS-4

## G4-TES

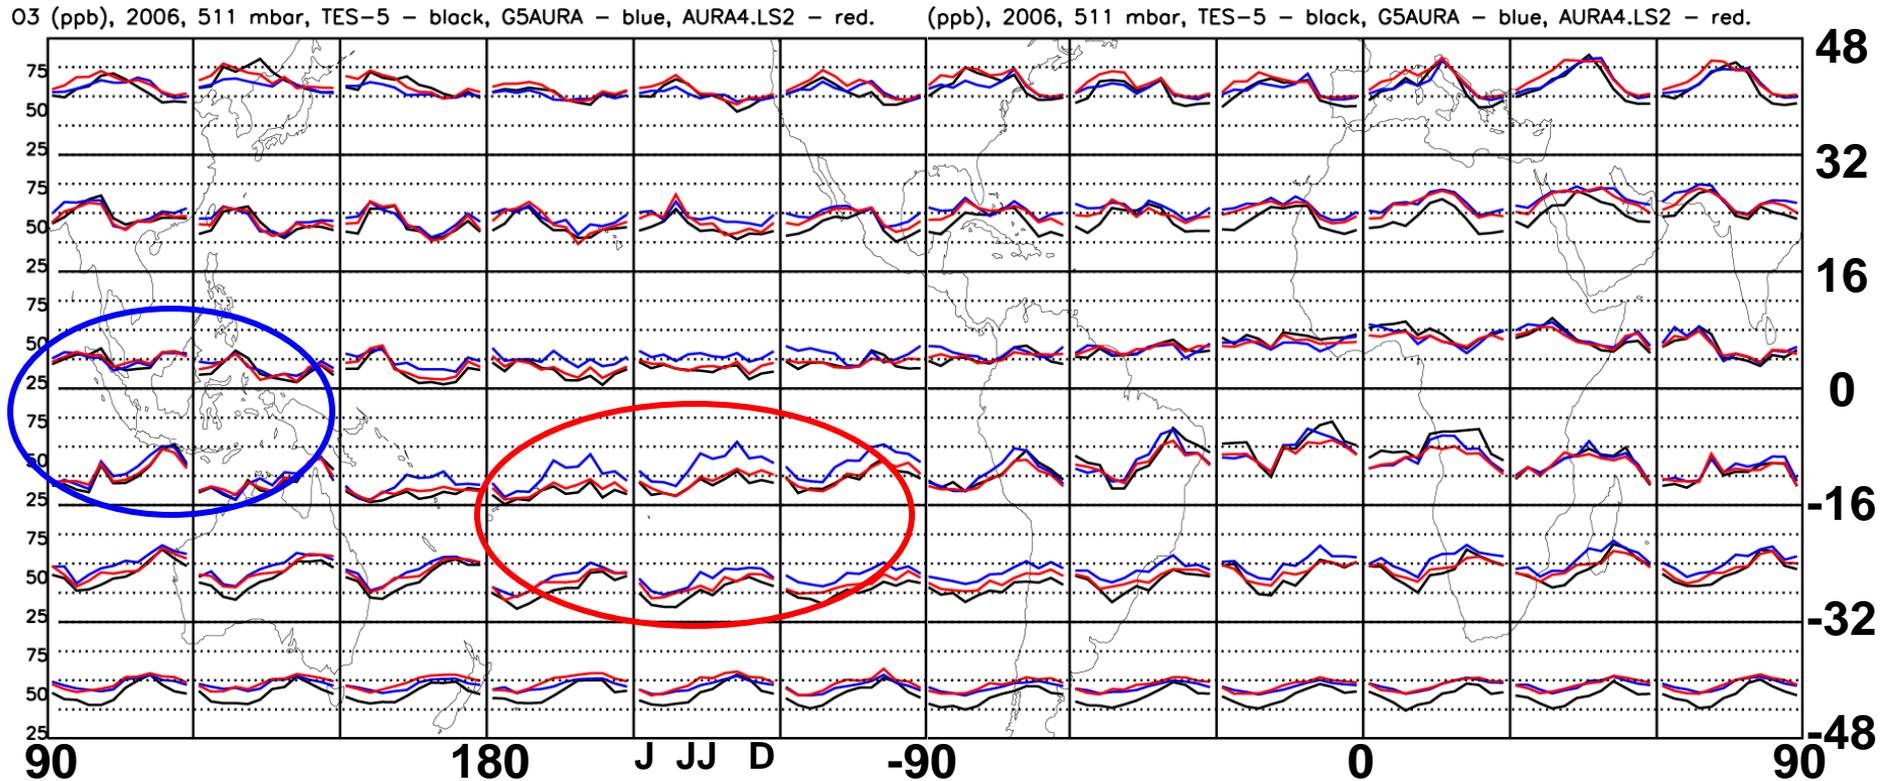

## GEOS-5

## G5-TES

**Sonde profiles**  
**GEOS-5**  
**GEOS-4**

# Models match month-month variability of TES ozone at 500 hPa

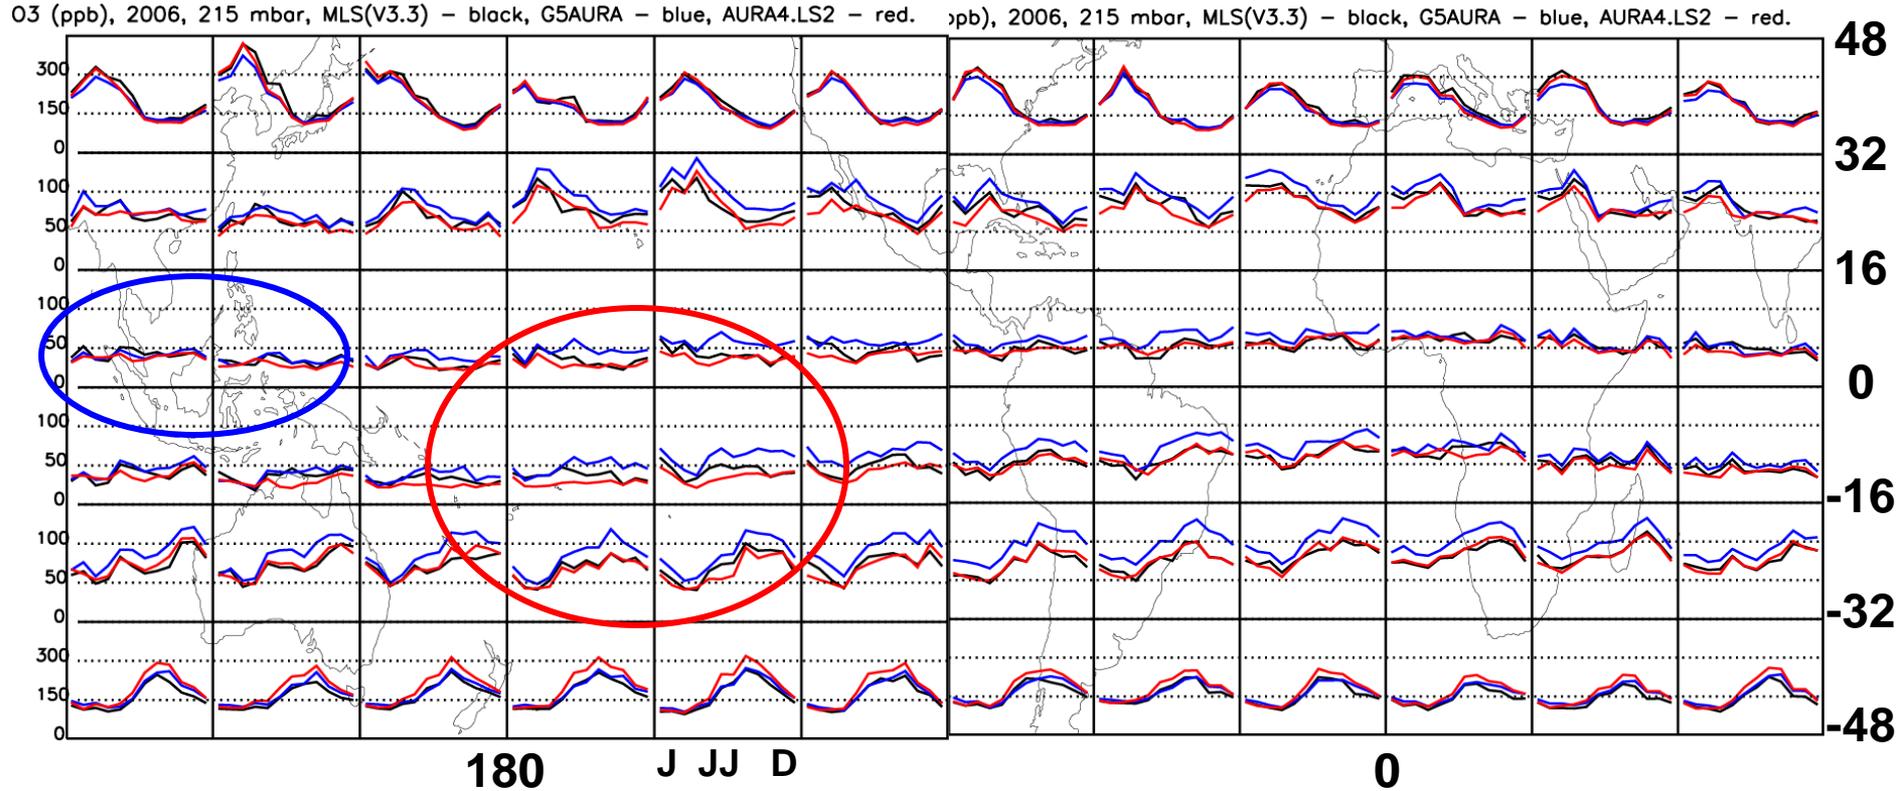

Each panel shows ozone for Jan. to Dec. from TES, GEOS-4 and GEOS-5

TES (minus 5 ppb)  
GEOS-4  
GEOS-5

GEOS-5 > GEOS-4 mid-year, mid-Pacific  
GEOS-5  $\approx$  GEOS-4, maritime continent

# Models match month-month variability of MLS ozone at 215 hPa

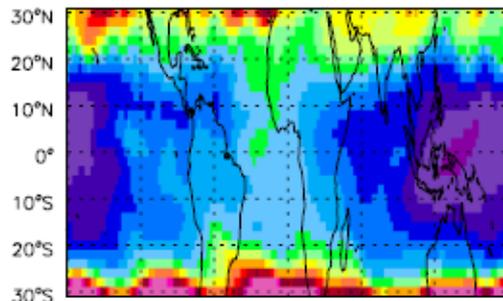

**MLS**  
**GEOS-4**  
**GEOS-5**

**GEOS-5 > GEOS-4 in much of the tropics**  
**GEOS-5  $\approx$  GEOS-4 in maritime continent**  
**GEOS-4 is usually closer to the MLS observations**

# Case study: Ozone in July

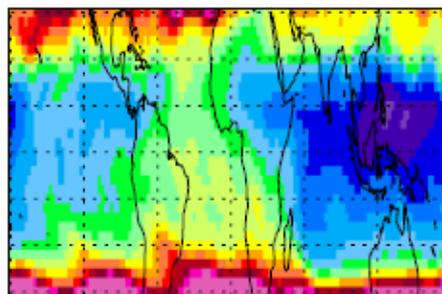

## GEOS-4

AURA4.LS2 July 2006 O3(ppb) 200 hPa

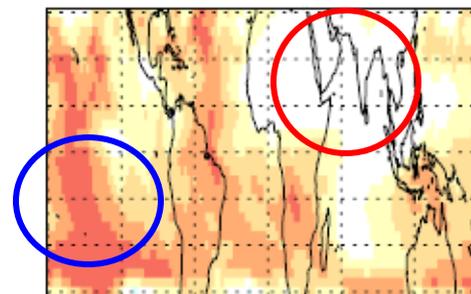

## GEOS-5

G5AURA July 2006 O3(ppb) 200 hPa

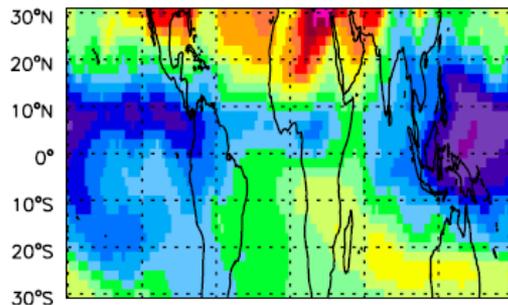

## G5-G4

G5-G4 July 2006 O3(ppb) 200 hPa

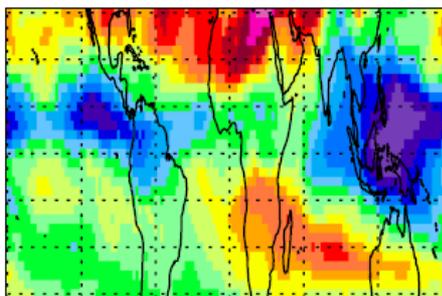

200 hPa

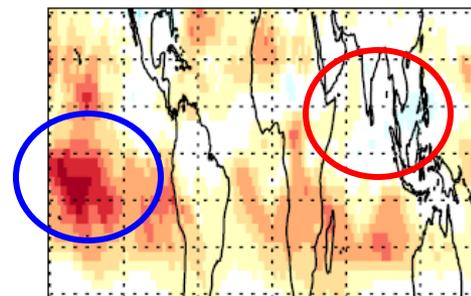

AURA4.LS2 July 2006 O3(ppb) 500 hPa

G5-G4 July 2006 O3(ppb) 500 hPa

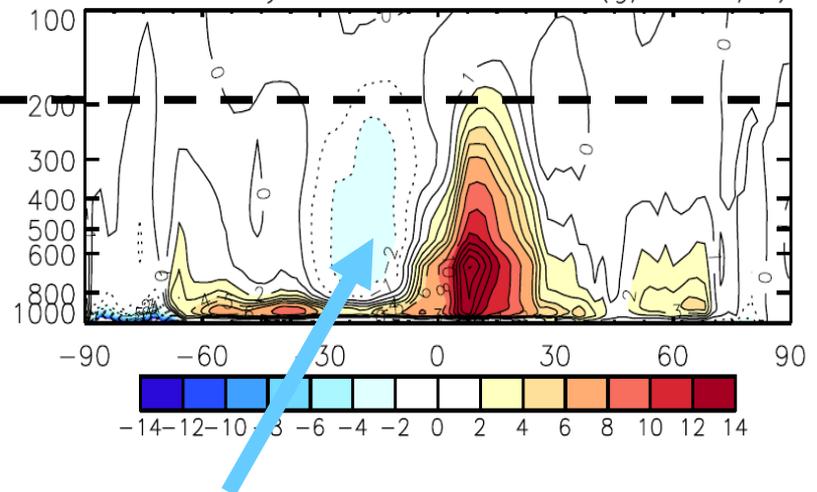

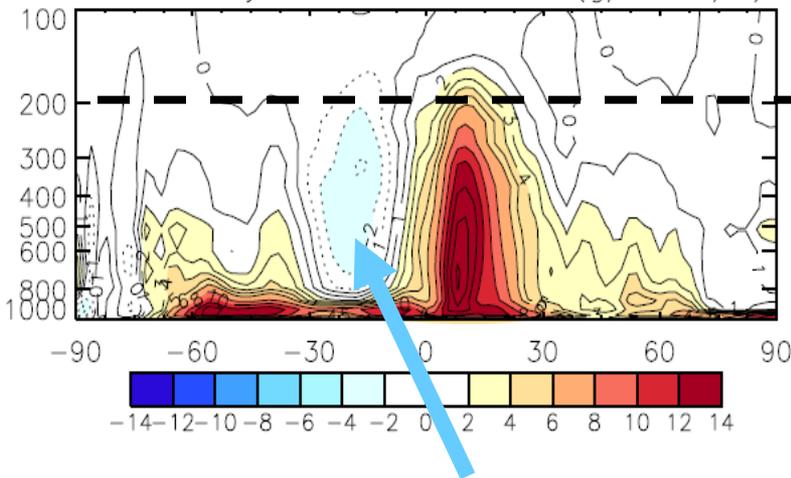

500 hPa

# Vertical transport of air, zonal mean, July 2006

## Convective mass flux ( $\text{g}/\text{m}^2/\text{sec}$ )

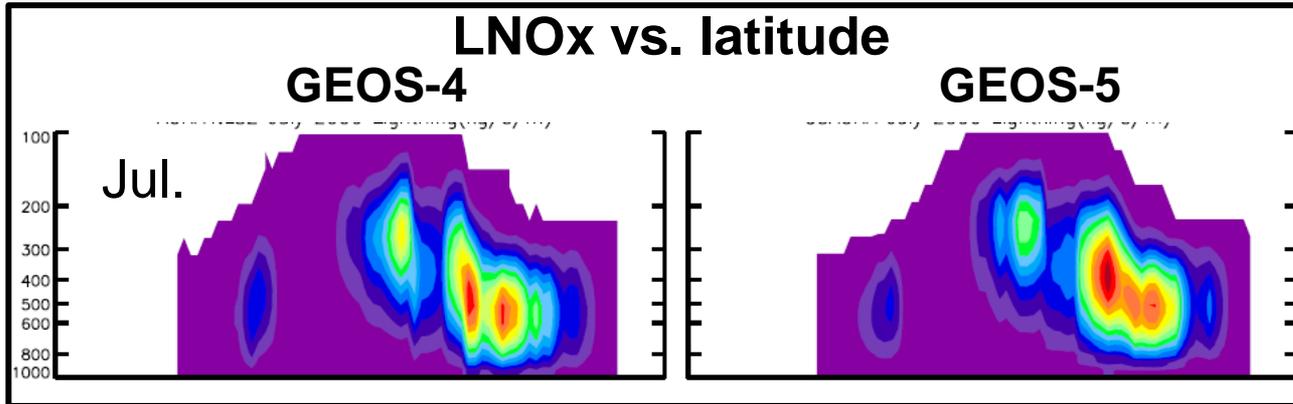

## Vertical mass flux: convection plus advection

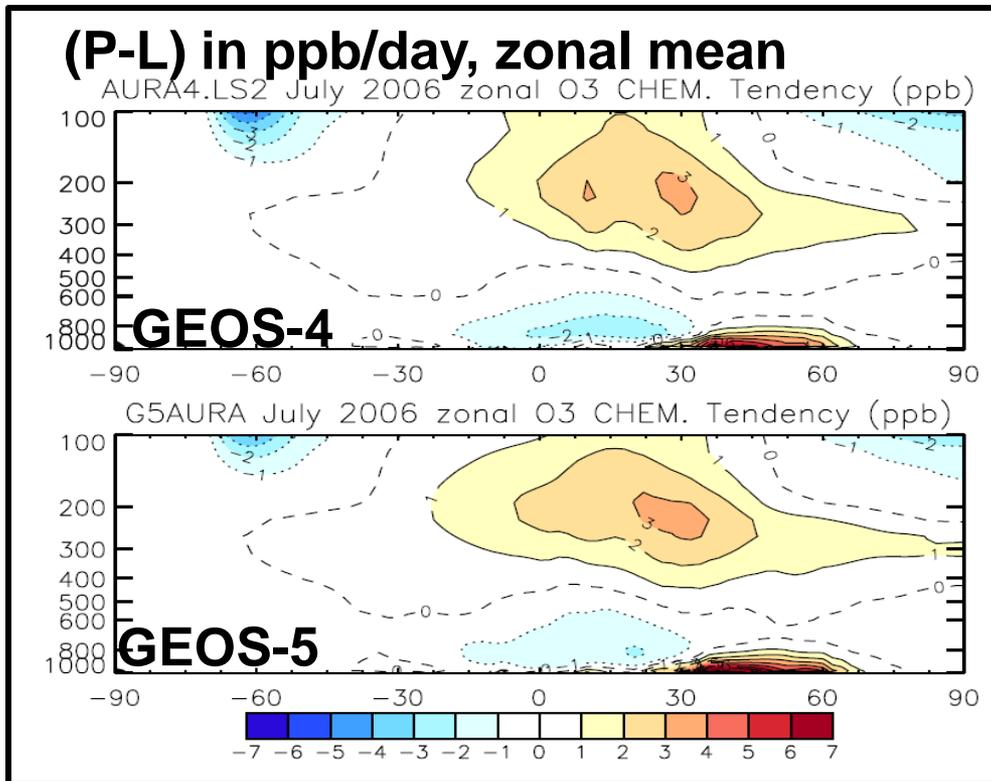

**Subsidence in southern sub-tropics (Hadley cell)**

**Red = upward flux, blue = subsidence**

# Lightning NOx (LNOx) emissions and (P-L) are similar

LNOx emissions have a similar vertical profile even though the mass fluxes peak at a lower altitude in GEOS-5.

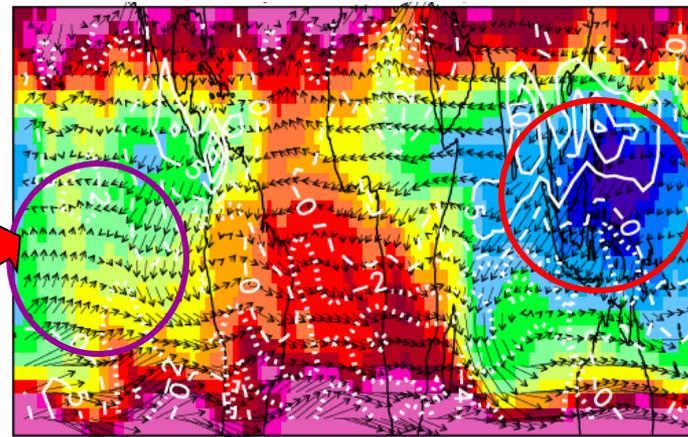

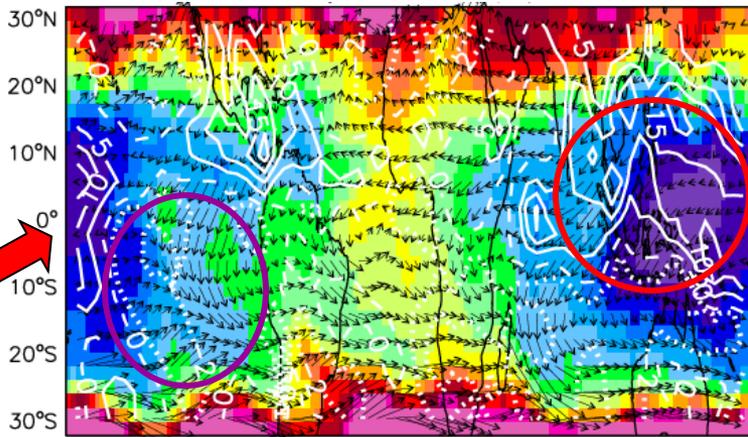

The top of the LNOx profile is determined from the top level with any cloud mass flux (or detrainment) – an extrema

# GEOS-4 vs. GEOS-5 ozone: similar in regions of deep convection, most different in regions of subsidence

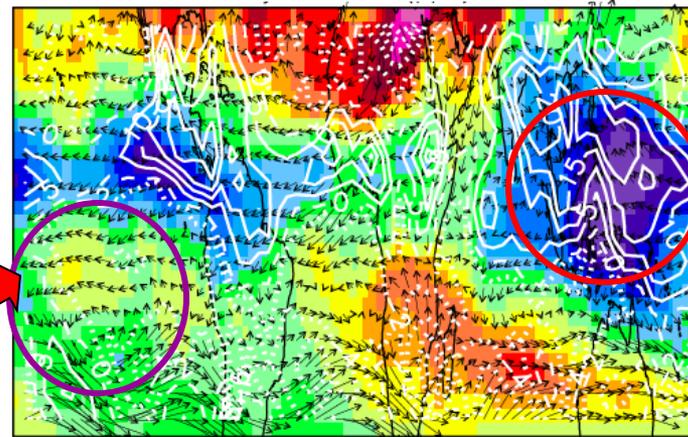

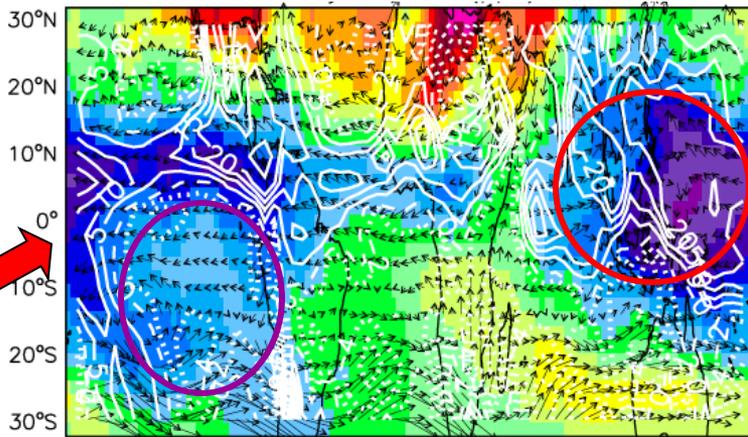

**GEOS-4**

**GEOS-5**

**200 hPa**

→ 30.0 m/s

→ 30.0 m/s

**500 hPa**

**White lines: air mass flux, solid=up, dotted=down; arrows are winds**

Ozone chemical tendency (P-L) is higher in GEOS-5 in regions of subsidence at 200 hPa – caused by higher NOx

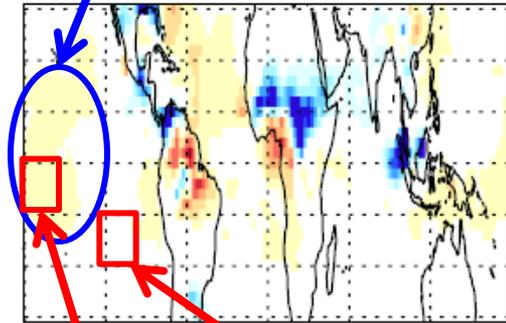

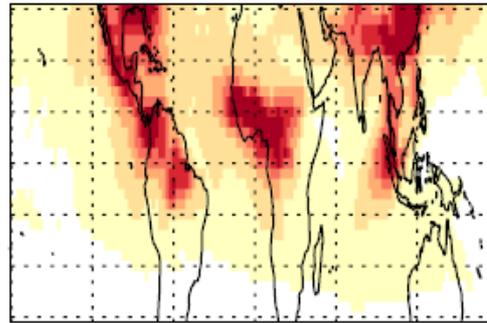

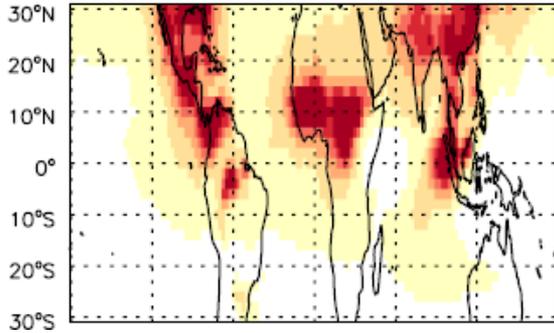

July 2006, 200 hPa

>0.5 ppb/day more ozone formed in GEOS-5

GEOS-4

GEOS-5

G5-G4

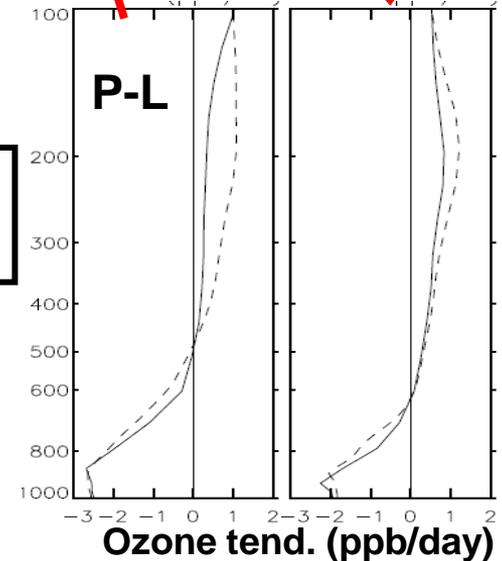

Ozone tendency (ppb/day)

Net production of ozone is highest over the lightning source regions - but rapid vertical mixing by convections leads to lower ozone in these regions.

GEOS-5: dashed  
GEOS-4: solid

## Concluding remarks

- **GEOS-4 and GEOS-5 ozone are similar in regions of deep convection, and are most different in regions of subsidence**
- **TES, MLS, and sonde data show that vertical transport in GEOS-5 degrades the tropical simulations compared to GEOS-4**
- **Conventional view that lightning NO<sub>x</sub> is the main factor controlling tropical ozone is overly simplistic – transport is also key, affecting ozone and its precursors**
- **What would the effect be of releasing LNO<sub>x</sub> at lower altitudes (Bousserez study)?? Ozone would increase in the mid-trop.**
- **Do the same problems exist in the GEOS-5 GCM using the same convective scheme? Coupled chemistry-climate models used for projections, so the stakes are high.**
- **What about GEOS-6?**
